

**I built my theory as a  
working model.**

**It disagreed with me  
seven times.**

A simulation of how people read intent,  
and where it breaks.

# The same object. One word changed.

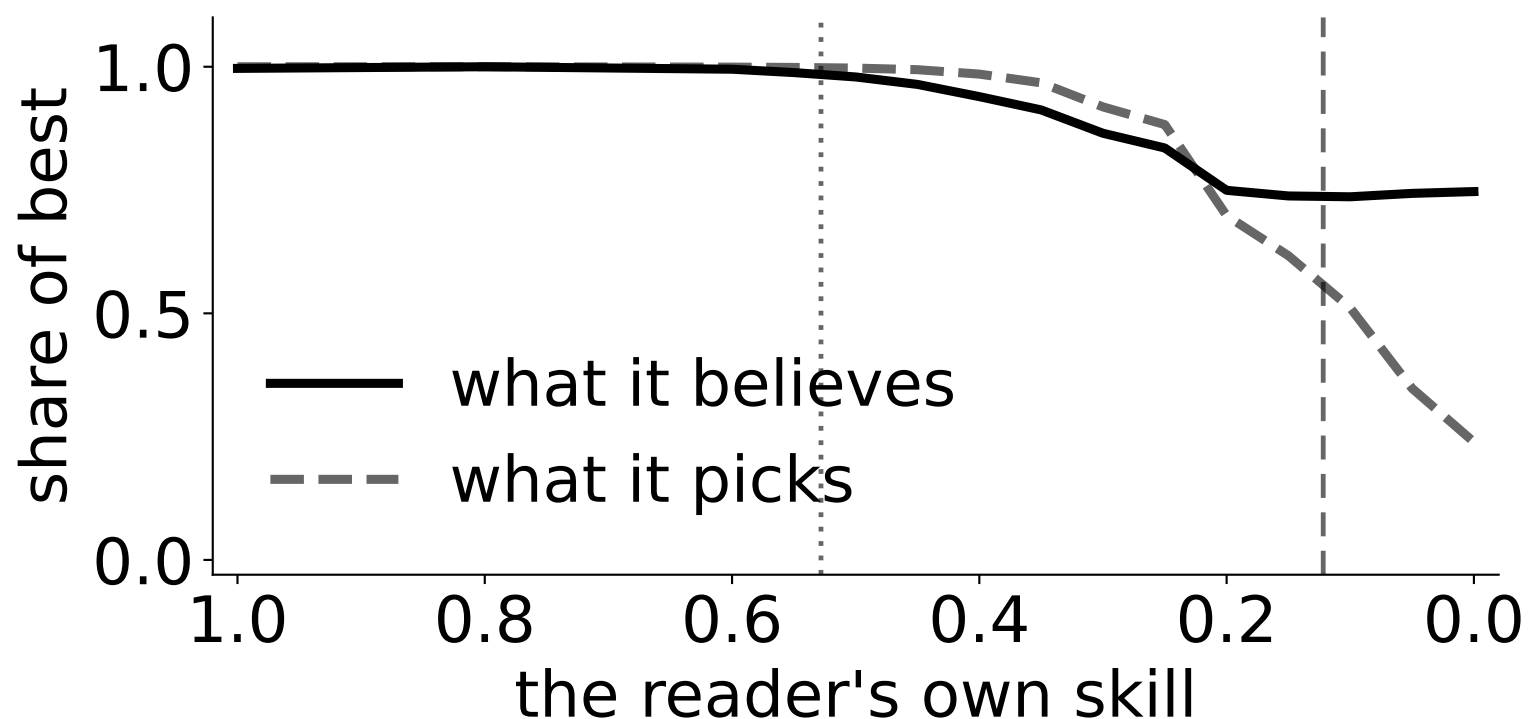

Identical machine-made content. Only the label differs.

CEILING: this reader cannot doubt the label it conditioned on, so the multiple is an UPPER BOUND. Rebuilt independently, the direction holds and the multiple does not. Read the direction, not the number.

Also: changes under exact inference (VALIDATION.md); effect size is solver-dependent.

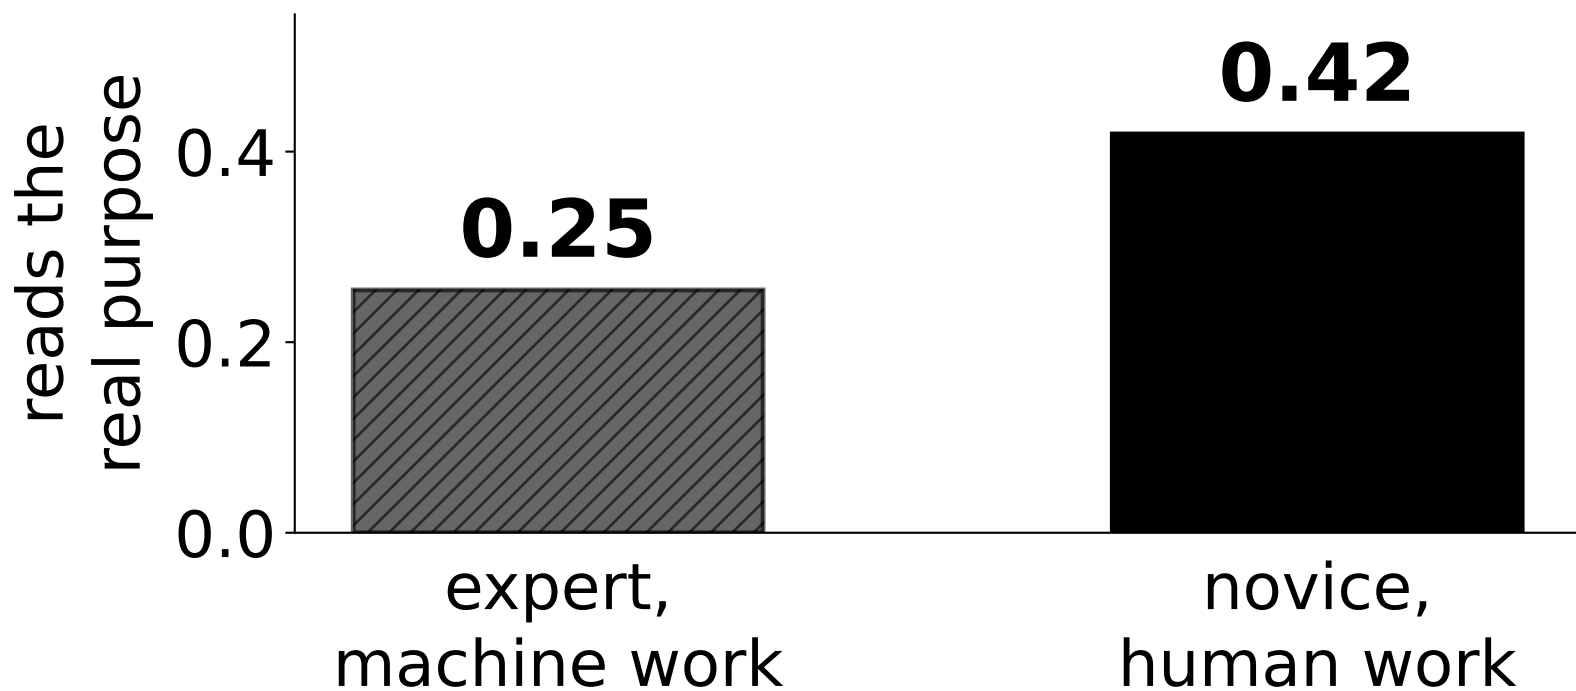

# Same documents. Only the reader changed.

No machine-made content anywhere in this test.  
Hold the documents constant, vary only who is reading, and what can be recovered collapses.

And what the reader believes starts coming apart at skill 0.53, long before its answers do at 0.12.  
Preference data collects answers.

# A novice looking at a person beats an expert looking at a machine.

Matched so both face the same information deficit.  
A badly aimed template still points near the truth. Content out of range points nowhere.

The expert keeps working at it (0.61 of the time) and stays lost. The novice quits at once (0.001) and feels settled.

# **Seven ideas died. One was mine.**

One experiment failed its own  
test three times and I didn't  
report it.
